CUHK

The views expressed here are those of the authors and do not necessarily reflect the views of the Bank of Japan.

When does inventor mobility raise welfare?

- "Mobility of personnel among firms provides a way of spreading information" (Arrow, 1962)

- Non-compete clauses affect inventor mobility, as in Silicon Valley against Route 128 (Gilson, 1999)
- German inventors' annual job-to-job rate fell from 12.5% in 2001 to 4.8% in 2014

\+ Inventors move to firms that value them more (reallocation)

\+ The destination absorbs the source's knowledge (diffusion)

– Search is costly, and search and innovation externalities distort mobility

Empirical facts motivate the model

- German employer–employee matched data linked to patent records
- Patent-listed inventors often move to lower-mean-wage establishments
- Inventors move down more often than other workers yet receive larger wage gains
- A firm-wage job ladder, in which moves go to higher-wage employers, generates neither fact
- An endogenous growth model with on-the-job search, in which a move transfers knowledge
- That knowledge makes moves to less productive firms profitable

Counterfactual Exercises and Main Results

- A non-compete ban raises inventor mobility and the annual growth rate
- The 2001–2014 mobility decline lowers the annual growth rate by 0.25 pp
- Knowledge diffusion, not reallocation, drives most of both growth effects
- A non-compete ban lowers consumption-equivalent (CE) welfare by 0.41%

  - Moves between incumbent firms that transfer knowledge

Empirical Results

German Inventor and Worker Data

- **INV-BIO.** 152,350 inventors on EPO filings 1999–2011, linked to social-security employment biographies 1980–2014
- **SIAB.** A 2% random sample of the same records (1,940,962 individuals), without patents
- The two data sets cannot be linked

Fact 1: Many inventor moves go to lower-wage establishments

Inventor moves by establishment mean-wage bin (row %)

	Destination rank bin									
Origin	1	2	3	4	5	6	7	8	9	10
1	18	16	13	12	10	9	7	6	5	4
2	11	16	14	12	10	9	8	8	7	6
3	7	13	14	12	10	9	9	9	8	8
4	6	10	11	12	11	11	11	10	10	8
5	5	8	9	11	11	11	10	12	11	12
6	4	7	9	9	10	12	13	12	12	11
7	4	6	7	8	9	11	13	13	14	15
8	3	5	6	7	10	11	14	13	14	17
9	2	5	5	6	9	9	14	14	16	21
10	2	3	4	4	6	7	10	12	19	32

- Ranked by mean wage, 36% of inventor moves go to a lower bin
- Ranked by citation productivity, moves also show no clear upward pattern
- Both patterns hold among moves that raise the inventor's own wage

INV-BIO, 1980–2014, inventor job-to-job moves. Establishments ranked within year by previous-year mean wage, in ten bins formed by cumulative inventor counts.

Fact 2: Inventor-proxy movers move down more often yet earn more

	Move to lower-mean-wage establishment	Own-wage growth
Inventor proxy $I_{i,t-1}$	0.0080^{***}	0.0581^{***}
	(0.0021)	(0.0033)

SIAB job-to-job movers, $N = 651{,}554$. Standard errors two-way clustered by origin and destination establishment.

- Inventor proxies are workers with a university-entrance qualification in the five occupation groups most common among inventors
- Controls: age, age squared, gender, log wage; origin, destination, and year FE
- A firm-wage job ladder, in which moves go to higher-wage employers, generates neither fact

Model

Heterogeneous Firms with Knowledge Capital and Inventors

- Continuum of firms with
  1. continuum mass of knowledge capital (or product lines) k
  2. continuum mass of inventors n
- Fixed total mass of inventors N
- Instantaneous payoff

$$\pi k - c\left(\frac{\hat{v}}{k}\right)k$$

  - π: profit per product line
  - $\hat{v}$: vacancy to search inventors
  - $c(\cdot)$: increasing and convex

$d\log k$ = Internal R&D + Knowledge Diffusion

1. Internal R&D ($-$ Destruction)

$$d\log k|_{\text{R\&D}} = \left(\underbrace{\mu\left(n/k\right)}_{\text{Internal R\&D}} - \underbrace{\delta}_{\text{Destruction}} - \frac{\sigma^2}{2} \right) dt + \underbrace{\sigma dW}_{\text{Shocks}}$$

   - $\mu(\cdot)$: non-negative, increasing, and concave
   - δ: endogenous in GE
   - Reminiscent of Klette and Kortum (2004)
   - $\underbrace{\mu\left(n/k\right)k/n}_{\text{R\&D outcome per inventor}}$ is increasing in $k/n \to k/n$: inventor productivity

2. Knowledge diffusion through inventor moves
   - When an inventor moves from a (k', n')-firm to a (k, n)-firm, the hiring firm gains the inventor and $\alpha(k/n, k'/n')$ units of knowledge capital: $\Delta n = 1$, $\Delta k = \alpha(k/n, k'/n')$
   - The source firm keeps its knowledge capital

Matching Technology

- Random search
- Only on-the-job search
- Labor market tightness $\theta = (\text{Total mass of vacancies } V) / (\text{Total mass of inventors } N)$
- A vacancy meets an inventor at rate $q(\theta)$
- An inventor meets a vacancy at rate $\theta q(\theta)$

Bargaining and Non-Compete Enforcement

Assumption.

1. In a meeting, the match is formed if the match surplus is positive
2. Poaching firm receives share $(1-\beta)$ of the match surplus, and the poached firm and its inventor receive share β
3. Vacancy posting decision maximizes the joint value of firm and incumbent inventors

- A non-compete clause secures share β for the poached firm and its inventor (Shi, 2023)
- Without an enforceable clause, Bertrand competition gives $\beta = 0$, so a ban lowers β to 0
- Assumptions follow Lentz and Mortensen (2022); Bilal et al. (2022) microfound assumption 3
- Under these assumptions, the firm's state is (k, n), not the distribution of wage contracts

HJB Equation

$\Omega(k,n,t)$: joint value of n inventors and firm with knowledge capital k

$$r(t)\Omega(k,n,t) - \frac{\partial}{\partial t}\Omega(k,n,t) =$$

$$\max_{\hat{v}\geq 0} \underbrace{\pi k - c\left(\frac{\hat{v}}{k}\right)k}_{\text{Profit}-\text{Search cost}} + \underbrace{\{\mu(n/k) - \delta\}k\Omega_k(k,n,t) + \frac{\sigma^2}{2}k^2\Omega_{kk}(k,n,t)}_{\text{Internal R\&D}-\text{Destruction}}$$

$$+ \underbrace{(1-\beta)q(\theta)\hat{v}\int \hat{M}(k,n,k',n',t)dG_n(k',n',t)}_{\text{Poaching}} + \underbrace{\beta\theta q(\theta)n\int \hat{M}(k',n',k,n,t)dG_v(k',n',t)}_{\text{Being poached}}$$

$$\underbrace{\hat{M}(k,n,k',n',t)}_{\text{Matching Surplus}} = \left[\ \Omega_n(k,n,t) + \alpha(k/n,k'/n')\Omega_k(k,n,t) - \Omega_n(k',n',t)\ \right]^+$$

- $G_n(k',n',t)$: inventor-weighted firm distribution
- $G_v(k',n',t)$: vacancy-weighted firm distribution

A continuum of product lines makes $x = n/k$ a sufficient state variable

- $x \equiv n/k$ is inventors per product line; $x^{-1} = k/n$ is inventor productivity
- Klette and Kortum (2004): with discrete product lines, the variance of firm growth falls with size, so both k and n are state variables
- Here, with a continuum of product lines and proportional shocks, $d \log k$ and $d \log n$ depend only on x, and Ω is homogeneous of degree one in (k, n)
- Firms never lose all product lines, so the model abstracts from entry, exit, and unemployment

Simplified HJB Equation

In the steady state, the joint value per product line $S(x)$ satisfies

$$\rho S(x) = \max_{v \geq 0} \underbrace{\pi - c(v)}_{\text{Profit}-\text{Search cost}} + \underbrace{\{\mu(x) - \delta\}\{S(x) - xS_x(x)\} + \frac{\sigma^2}{2}x^2 S_{xx}(x)}_{\text{Internal R\&D}-\text{Destruction}}$$
$$+ \underbrace{(1-\beta)q(\theta)v\int M(x,x')dF_x(x')}_{\text{Poaching}} + \underbrace{\beta\theta q(\theta)x\int M(x',x)dF_v(x')}_{\text{Being poached}}$$

$$\underbrace{M(x,x')}_{\text{Matching surplus}} = \left[\ S_x(x) + \alpha(x,x')\{S(x) - xS_x(x)\} - S_x(x')\ \right]^+$$

- v: vacancy per product line; $F(x)$: distribution of product lines over x
- $F_x(x)$, $F_v(x)$: inventor-weighted and vacancy-weighted product line distributions

Knowledge makes downward moves profitable

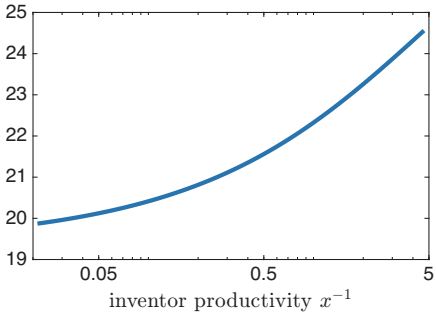

- With joint value $\Omega(k,n) = k\,S(x)$, a move from x' to x has match surplus

$$M(x,x') = \Big[\underbrace{S_x(x)}_{\substack{\text{destination}\\ \text{inventor value}}} + \underbrace{\alpha(x,x')\big\{S(x) - xS_x(x)\big\}}_{\text{value of the knowledge brought}} - \underbrace{S_x(x')}_{\substack{\text{source}\\ \text{inventor value}}} \Big]^+$$

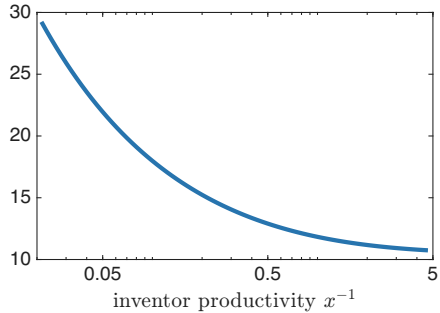

- If $\alpha = 0$, inventors move only to firms with higher inventor value S_x, as in a job ladder
- With $\alpha > 0$, a move to a firm with lower x^{-1} occurs when the value of the knowledge brought exceeds the loss in inventor value

Less productive firms value knowledge more

Inventor value $S_x(x)$ in the calibrated model

Knowledge value $S(x) - xS_x(x)$ in the calibrated model

- A move to a less productive firm loses little inventor value but gains much knowledge value

Mobility shapes growth through reallocation and diffusion

- Log utility and a quality ladder with step λ over a unit continuum of products give growth

$$g = \underbrace{\log(\lambda)}_{\text{innovation step}} \times \underbrace{(\delta_{RD} + \delta_{KD})}_{\text{creative destruction rate}}$$

$$\delta_{RD} = \int \mu(x)\, dF(x), \qquad \delta_{KD} = N\theta q(\theta) \iint \mathbb{1}_P(x, x')\, \alpha(x, x')\, dF_x(x')\, dF_v(x)$$

- $\mathbb{1}_P(x, x')$: equals 1 when poaching is profitable
- With concave R&D, internal-R&D growth is highest when inventors are spread evenly across product lines, so dispersion of inventor productivity lowers it
- Successful poaching moves source knowledge into destination firms

Sources of Private-Social Wedges

Private-social wedge	Source	Effect on private incentives
Innovation value	Appropriability	Too little private innovation value
Innovation value	Business stealing	Too much private innovation value
Vacancy posting	Hold-up from surplus sharing	Too few vacancies
Vacancy posting	Search congestion	Too many vacancies

Estimation

What INV-BIO Observes

- **Inventors.** Establishment and dates of each job, daily wage, occupation, education, and age
- **Patents.** Filing date, forward citation counts, co-inventors, and technology classes
- **Establishments.** Employment, mean wage, industry, and region

Functional Forms

Function	Description
$c(v) = \frac{\bar{c}}{\phi+1} v^{\phi+1}$	Vacancy cost function
$q(\theta) = \bar{q}\theta^{\eta-1}$	Matching function
$\mu(x) = \bar{\mu} x^{\varepsilon}$	Internal R&D function
$\alpha(x, x') = \bar{\alpha} x'^{-1}$	Knowledge diffusion function

From the Law of Motion to a Regression

- Inventor productivity $z \equiv x^{-1}$ is measured by $z_{e,t}$, three-year citations per inventor to patents filed at establishment e in year t
- $\alpha(x, x') = \overline{\alpha}\, z'$ and $\mu(x) = \overline{\mu}\, z^{-1/2}$, so a mover brings the fraction $\overline{\alpha}$ of the source firm's knowledge per inventor
- $z^{\text{inc}}_{e,t}$ is the productivity of inventors who stay at e from $t-1$ to t
- $m_{e' \to e,t}$ inventors move from e' to e between $t-1$ and t

$$\Delta \log z^{\text{inc}}_{e,t} = \underbrace{\overline{\alpha} \sum_{e'} \frac{m_{e' \to e,t}}{n_{e,t-1}} \frac{z_{e',t-1}}{z_{e,t-1}}}_{\text{diffusion exposure}} + 12\overline{\mu} \underbrace{z_{e,t-1}^{-1/2}}_{\substack{\text{R\&D} \\ \text{exposure}}} + \underbrace{\text{net inflow rate} + \text{FE}}_{\text{controls}} + \varepsilon_{e,t}$$

A move transfers 53% of the average knowledge per inventor

	Incumbent productivity growth		
	(1)	(2)	(3)
Diffusion exposure	0.526***	0.306***	0.250***
	(0.071)	(0.073)	(0.089)
R&D exposure $z_{e,t-1}^{-1/2}$	0.255***	0.347***	0.440***
	(0.023)	(0.024)	(0.029)
Establishment FE	Yes	Yes	Yes
Year FE	Yes	No	No
Industry × region × year FE	No	Yes	Yes
Establishment linear trend	No	No	Yes
Root MSE	0.702	0.641	0.653
Establishment-years	12,690	10,812	10,812

- Column (1), the model's moment net of establishment and year effects, sets

$$\overline{\alpha} = 0.526$$
$$\overline{\mu} = 0.2546/12 = 0.0212$$
$$\sigma = 0.702/\sqrt{12} = 0.203$$

- One move brings knowledge equal to 1.6 years of an inventor's internal R&D output

INV-BIO establishment-years with positive exposure, weighted by incumbent inventors; net inflow rate in all columns; standard errors clustered by establishment. Annual data, monthly model.

Robustness table

The source's productivity, not the mover's, drives the estimate

	Incumbent productivity growth		
	(1)	(2)	(3)
Source productivity, leave-one-mover-out	0.478***	0.273***	0.210**
	(0.070)	(0.080)	(0.099)
Mover's own productivity	0.048	0.040	0.036
	(0.030)	(0.039)	(0.049)
Establishment-years	12,628	10,757	10,757

INV-BIO establishment-years; fixed effects as in baseline columns (1)–(3); standard errors clustered by establishment.

- Without the mover, the source coefficient stays near the baseline estimate, while the mover's own coefficient is small

Predicted source-contraction inflows raise incumbent productivity

- Severe source contractions are allocated through hiring links two to six years earlier

$$\hat{m}_{e' \to e,t} = \underbrace{s_{e' \to e,t}}_{\substack{\text{share of } e'\text{'s} \\ \text{past moves to } e}} \times \underbrace{n_{e',t-1}\, \mathbb{1}\{\text{employment at } e' \text{ falls by at least 80\%}\}}_{\text{displaced inventors}}$$

- Predicted exposure replaces $m_{e' \to e,t}$ with $\hat{m}_{e' \to e,t}$ in the diffusion exposure

Regression on the predicted exposure	(1)	(2)	(3)
Incumbent productivity growth	0.0515**	0.0482**	0.0449
	(0.0200)	(0.0187)	(0.0295)
Realized diffusion exposure	0.0236**	0.0245*	0.0363
	(0.0117)	(0.0125)	(0.0231)

INV-BIO establishment-years ($N = 26{,}521$ in column 1); fixed effects as in baseline columns (1)–(3); standard errors clustered by establishment.

Calibration

Set externally or normalized		
ρ	0.004	Monthly discount rate (5% a year)
$\overline{c}$	1	Vacancy-cost scale, normalized
ϕ	3.45	Vacancy-cost curvature, Bilal et al. (2022)
η	0.50	Matching elasticity, Petrongolo and Pissarides (2001)
ε	0.50	R&D elasticity, Acemoglu et al. (2018)
π	0.23	Profit per product line (markup 1.3)
N	1.95	Inventors ($1/N = 0.512$ citations)
β	0.50	Baseline surplus share

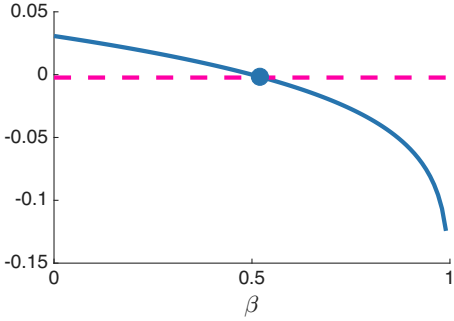

Regression, column (1)		
$\overline{\alpha}$	0.526	Knowledge diffusion
$\overline{\mu}$	0.0212	Internal R&D
σ	0.203	R&D shocks
Balanced-growth targets		
$\overline{q}$	0.0198	Job-to-job rate 12.5% (2001)
λ	1.053	Growth 2% a year

- With $\beta = 0.5$, a ban raises the job-to-job rate by 10.2%, close to Hawaii's 11% rise (Balasubramanian et al., 2022)

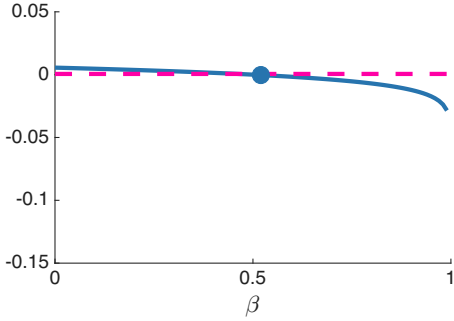

Quantitative Exercises

Stronger enforcement lowers growth, mostly through diffusion

Knowledge-diffusion growth, change from $\beta = 0.5$ (pp)

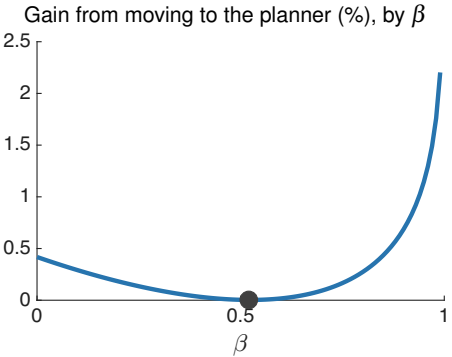

Internal-R&D growth, change from $\beta = 0.5$ (pp)

Steady states, annual rates on a common vertical scale. Solid: equilibrium; dashed: planner; dot: efficient split $\beta^* = 0.52$.

- A higher β lowers the poacher's share, vacancy posting, and the job-to-job rate
- Knowledge-diffusion growth is proportional to the job-to-job rate, $\delta_{KD} = \overline{\alpha}\,\theta q(\theta)$
- Internal-R&D growth responds only through productivity dispersion, which moves little

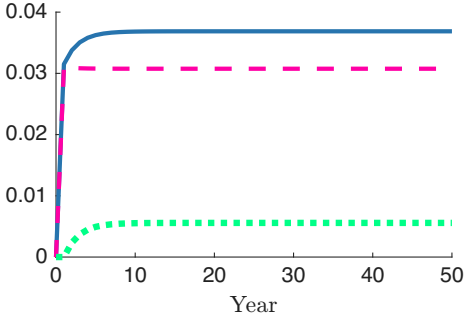

A fixed split nearly implements the planner

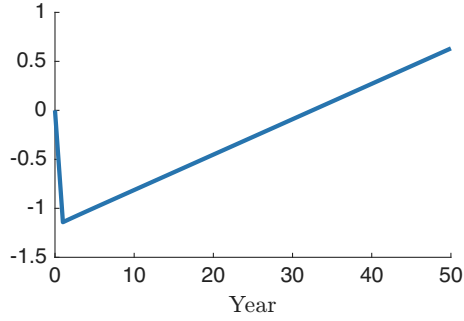

- For each β, the figure shows the CE gain from moving from its steady state to the planner
- The gain is smallest at $\beta^* = 0.52$, at 0.0029% of consumption
- A ban raises welfare only if the pre-ban surplus share exceeds 0.85

A ban raises growth and lowers welfare, starting from $\beta = 0.5$

Growth (pp): total, diffusion (dashed), R&D (dotted)

Log consumption, change from initial BGP ($\times 100$)

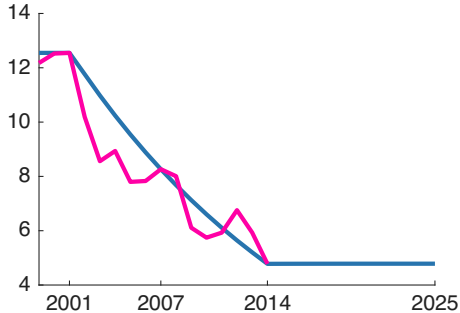

- β falls permanently from 0.5 to 0, and the job-to-job rate rises by 10.2%
- Long-run growth rises by 0.037 pp, 0.031 pp of it through knowledge diffusion
- Firms spend more on recruiting, so CE welfare falls by 0.41%

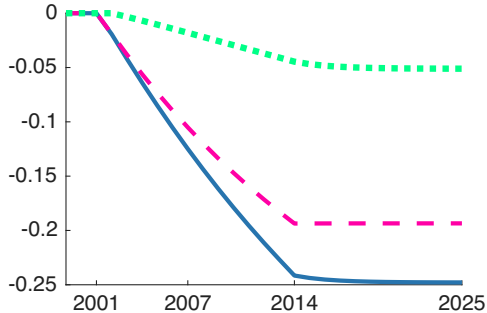

All transition panels Welfare measure

Declining inventor mobility lowers growth

Job-to-job rate (%): model (blue), data (magenta)

Growth (pp): total, diffusion (dashed), R&D (dotted)

- A path of matching efficiency matches the rates in 2001, 2007, and 2014 (12.5%, 8.3%, 4.8%)
- Long-run growth falls by 0.25 pp, 0.19 pp of it through knowledge diffusion
- CE welfare falls by 3.46%

Conclusion

- Inventors often move to lower-wage establishments yet gain more in wages than other movers
- A fixed split nearly implements the planner ($\beta^* = 0.52$)
- From $\beta = 0.5$, a ban raises growth and lowers welfare by 0.41%
- The 2001–2014 mobility decline lowers annual growth by 0.25 pp and welfare by 3.46%
- Knowledge diffusion, not reallocation, drives most of both growth effects

Appendix

Appendix contents

Empirical Appendix

- INV-BIO summary statistics
- Robustness of Fact 1
- SIAB and inventor proxies
- Inventor-proxy worker flows

Theoretical Appendix

- State variable x

Definition of Inventor-Proxy Workers

- Inventor-proxy workers: SIAB workers with a university-entrance qualification in the five largest KldB 2010 parent occupation groups among INV-BIO inventors
  - Machine and vehicle technology (25)
  - Mechatronics, energy and electrical engineering (26)
  - Technical R&D, design and production planning (27)
  - Mathematics, biology, chemistry and physics (41)
  - Business management and organisation (71)
- These groups account for 80.5% of inventor-years with observed occupations

Inventor-Proxy Workers in SIAB and Inventors in INV-BIO

Summary statistics (1980–2014)		SIAB Workers	SIAB Inventor-proxy workers	INV-BIO Inventors
Wage, Euro	Mean	63.8	99.5	123.8
	S.D.	45.5	55.6	52.1
Age	Mean	38.5	39.0	38.9

University-entrance qualification, %		15.3	100.0	70.3
N of observations, thousand		17,474	1,030	3,517

Inventor-proxy workers are workers whose observed KldB 2010 parent occupation group is 25, 26, 27, 41, or 71 and who have a university-entrance qualification.

Inventor Mobility Relative to General Workers

- Compare inventor-proxy workers with other job-to-job movers

$$y_{it} = b\, I_{i,t-1} + X'_{i,t-1}\gamma + \mathrm{FE}_{o(i)} + \mathrm{FE}_{d(i)} + \mathrm{FE}_t + \varepsilon_{it}$$

- y_{it}: lower-mean-wage destination or wage growth
- Sample: BeH-to-BeH establishment changes without unemployment spell
- $X_{i,t-1}$: age, age squared, gender, and log wage

Back to Fact 2

Inventor-Proxy Worker Flows: Wage-Increase Moves

	Wage-increase job-to-job sample	
	(1)	(2)
Dependent variable	D_{it}^{wage}	$\Delta \log w_{it}$
$I_{i,t-1}$	0.0094***	0.0535***
	(0.0025)	(0.0027)
Controls	Yes	Yes
Origin estab. FE	Yes	Yes
Dest. estab. FE	Yes	Yes
Year FE	Yes	Yes
Observations	404,722	404,722
Adjusted R^2	0.5678	0.7002

Sample is restricted to establishment changes with an increase in the worker's own daily wage. Other definitions match the full job-to-job sample.

Back to Fact 2

Inventor Mass per Product Line x as State Variable

- $x \equiv n/k$: inventor mass per product line
- $x^{-1} = k/n$: inventor productivity
- $f(x)$: distribution of product lines over x
- $S(x)$: joint value of x mass of inventors and unit mass of product line

$$\underbrace{kg(k,n)}_{\text{\# of product line} \times \text{Firm distribution}} = \underbrace{f(x)}_{\text{Product distribution}}$$

$$\underbrace{\Omega(k,n)}_{\text{Firm-level joint value}} = \underbrace{kS(x)}_{\text{\# of product line} \times \text{Product-level joint value}}$$

$$\underbrace{\Omega_n(k,n)}_{\text{Marginal value of inventor}} = \underbrace{S_x(x)}_{\text{Inventor per product line} \uparrow}$$

$$\underbrace{\Omega_k(k,n)}_{\text{Marginal value of knowledge capital}} = \underbrace{S(x)}_{\text{Product line} \uparrow} \quad \underbrace{-xS_x(x)}_{\text{Inventor per product line} \downarrow}$$

Back to simplified HJB

Aggregation Setting

- Representative household utility

$$\int_0^\infty e^{-\rho t} \log C(t) dt$$

- Inelastically supplies L units of production labor and N inventors
- Aggregate output

$$\log Y(t) = \int_0^1 \log \left(a(\omega, t) l(\omega, t) \right) d\omega$$

  - $a(\omega, t)$: productivity of product ω
  - $l(\omega, t)$: production labor used to produce product ω (no friction)

- Arrival of creative destruction is random across product lines
- Innovation step size is $\lambda > 0$

BGP Equilibrium 1

A stationary competitive equilibrium consists of sequence of joint value, vacancy policy, poaching indicator function, inventor productivity distribution, creative destruction rate, and labor market tightness $\left[\left\{S(x), v(x), \{\mathbb{1}_P(x,x')\}_{x'\in(0,\infty)}, f(x)\right\}_{x\in(0,\infty)}, \delta, \theta\right]$ such that

- The joint value $S(x)$ satisfies the HJB equation

$$\begin{aligned}\rho S(x) =& \pi - c(v(x)) + \{\mu(x) - \delta\}\{S(x) - xS_x(x)\} + \frac{\sigma^2}{2}x^2 S_{xx}(x) \\ &+ (1-\beta)q(\theta)v(x)\int M(x,x')dF_x(x') + \beta\theta q(\theta)x\int M(x',x)dF_v(x')\end{aligned}$$

where the matching surplus $M(x,x')$ is given by

$$M(x,x') = \left[S_x(x) + \alpha(x,x')\{S(x) - xS_x(x)\} - S_x(x')\right]^+$$

BGP Equilibrium 2

- The vacancy posting is optimal, so that $v(x,t)$ satisfies

$$c'(v(x)) = (1-\beta)\, q(\theta) \int M(x,x')dF_x(x')$$

- Given a match, the inventor moves if the match surplus is positive:

$$\mathbb{1}_P(x,x') = \begin{cases} 1 & \text{if} \quad M(x,x') > 0 \\ 0 & \text{otherwise} \end{cases}$$

BGP Equilibrium 3

- The inventor productivity distribution $f(x,t)$ follows the KF equation

$$
\begin{aligned}
0 = & \left\{ \begin{array}{c} \mu(x) - \delta \\ +q(\theta) v(x) \int \mathbb{1}_P(x,x') \alpha(x,x') \, dF_x(x') \end{array} \right\} f(x) \\
& - \frac{\partial}{\partial x} \left[\left\{ \begin{array}{c} -\{\mu(x) - \delta\} x \\ +q(\theta) v(x) \int \mathbb{1}_P(x,x') \{1 - \alpha(x,x')x\} \, dF_x(x') \\ -\theta q(\theta) x \int \mathbb{1}_P(x',x) dF_v(x') \end{array} \right\} f(x) \right] \\
& + \frac{\partial^2}{\partial x^2} \left[\frac{\sigma^2}{2} x^2 f(x) \right],
\end{aligned}
$$

- The labor market tightness θ and the creative destruction rate δ satisfy

$$
\begin{aligned}
N\theta &= \int v(x) f(x) \, dx \\
\delta &= \int \mu(x) \, dF(x) + N\theta q(\theta) \int \int \mathbb{1}_P(x,x') \alpha(x,x') \, dF_x(x') dF_v(x)
\end{aligned}
$$

Social Optimum

$$\rho S^*(x) = \max_{v \geq 0} \underbrace{\pi^*}_{\text{Growth externality}} - c(v(x)) + \{\mu(x) - \delta\}\{S^*(x) - xS_x^*(x)\} + \frac{\sigma^2}{2}x^2 S_{xx}^*(x)$$

$$+ \underbrace{\theta q'(\theta) v(x) \int\int M^*(x,x')\ dF_x(x') dF_v(x)}_{\text{Congestion externality}}$$

$$+ \underbrace{q(\theta) v(x) \int M^*(x,x')\, dF_x(x') + \theta q(\theta) x \int M^*(x',x)\, dF_v(x')}_{\text{Hold-up problem}}$$

- Externality from Schumpeterian growth: appropriability effect + business stealing effect
- Externality from random search: congestion externality + hold-up problem

Social Planner's Problem

$$\mathbf{x}(t) = \left[\log Y(t), \{f(x,t)\}_{x\in(0,\infty)}\right]$$

$$\mathbf{y}(t) = \left[\delta(t), \theta(t), \{v(x,t)\}_{x\in(0,\infty)}, \left\{\mathbb{1}_P(x,x',t)\right\}_{x,x'\in(0,\infty)}\right]$$

$$\boldsymbol{\lambda}_{\mathbf{x}}(t) = \left[\lambda_Y(t), \{\lambda_f(x,t)\}_{x\in(0,\infty)}\right]$$

$$\boldsymbol{\lambda}_{\mathbf{y}}(t) = [\lambda_\delta(t), \lambda_\theta(t)]$$

Back to social optimum

Social Planner's Problem

$$
\begin{aligned}
&\mathscr{H}^{P}\left(\mathbf{x}(t),\mathbf{y}(t),\boldsymbol{\lambda}_{\mathbf{x}}(t),\boldsymbol{\lambda}_{\mathbf{y}}(t)\right)\\
&=\ln Y(t)+\ln\left\{1-\int c\left(v\left(x,t\right)\right)dF(x,t)\right\}\\
&\quad+\lambda_{Y}(t)\,\delta(t)\ln\lambda\\
&\quad+\lambda_{\delta}(t)\left[-\delta(t)+\int\left\{\mu(x)+q(\theta(t))v(x,t)\int\mathbb{1}_{P}(x,x',t)\alpha\left(x,x'\right)dF_{x}(x',t)\right\}dF(x,t)\right]\\
&\quad+\lambda_{\theta}(t)\left\{N\theta(t)-\int_{0}^{\infty}v(x,t)\,f(x,t)dx\right\}\\
&\quad+\int_{0}^{\infty}\lambda_{f}(x,t)\left[\begin{array}{c}\left\{\begin{array}{c}q(\theta(t))v(x,t)\int\mathbb{1}_{P}(x,x',t)\alpha(x,x')\,dF_{x}(x',t)\\+\mu(x)-\delta(t)\end{array}\right\}f(x,t)\\-\frac{\partial}{\partial x}\left[\left\{\begin{array}{c}q(\theta(t))v(x,t)\int\mathbb{1}_{P}(x,x',t)\left\{1-\alpha(x,x')x\right\}dF_{x}(x',t)\\-\theta(t)\,q(\theta(t))x\int\mathbb{1}_{P}(x',x,t)dF_{v}(x',t)\\-\left\{\mu(x)-\delta(t)\right\}x\end{array}\right\}f(x,t)\right]\\+\frac{\partial^{2}}{\partial x^{2}}\left[\frac{\sigma^{2}}{2}x^{2}f(x,t)\right]\end{array}\right]dx
\end{aligned}
$$

Back to social optimum

Social Planner's Problem

$$
\begin{aligned}
0 &= \frac{\partial}{\partial \mathbf{y}(t)} \mathscr{H}^P\left(\mathbf{x}(t), \mathbf{y}(t), \boldsymbol{\lambda}_{\mathbf{x}}(t), \boldsymbol{\lambda}_{\mathbf{y}}(t)\right) \\
\rho \boldsymbol{\lambda}_{\mathbf{x}}(t) - \dot{\boldsymbol{\lambda}}_{\mathbf{x}}(t) &= \frac{\partial}{\partial \mathbf{x}(t)} \mathscr{H}^P\left(\mathbf{x}(t), \mathbf{y}(t), \boldsymbol{\lambda}_{\mathbf{x}}(t), \boldsymbol{\lambda}_{\mathbf{y}}(t)\right) \\
0 &= \frac{\partial}{\partial \boldsymbol{\lambda}_{\mathbf{y}}(t)} \mathscr{H}^P\left(\mathbf{x}(t), \mathbf{y}(t), \boldsymbol{\lambda}_{\mathbf{x}}(t), \boldsymbol{\lambda}_{\mathbf{y}}(t)\right) \\
\dot{\mathbf{x}}(t) &= \frac{\partial}{\partial \boldsymbol{\lambda}_{\mathbf{x}}(t)} \mathscr{H}^P\left(\mathbf{x}(t), \mathbf{y}(t), \boldsymbol{\lambda}_{\mathbf{x}}(t), \boldsymbol{\lambda}_{\mathbf{y}}(t)\right) \\
0 &= \lim_{t \to \infty} \left[\exp\left(-\rho t\right) \boldsymbol{\lambda}_{\mathbf{x}}(t) \mathbf{x}(t)\right]
\end{aligned}
$$

Back to social optimum

Optimal Instantaneous Profit

$$\underbrace{\frac{\ln \lambda}{\rho}\left[1-\int_0^{\infty} c(v(x))\, f(x) dx\right]}_{\text{marginal gain from innovation}} = \underbrace{\int_0^{\infty} \left[S^*(x) - S_x^*(x)\, x\right] f(x) dx}_{\text{expected marginal value of knowledge}}$$

Back to social optimum

Decomposition of Firm Growth

$$d\log x^{-1}(x,t) = d\log k(x,t) - d\log n(x,t)$$

$$d\log k(x,t) = \underbrace{q(\theta(t))v(x,t)\int \mathbb{1}_P(x,x',t)\alpha(x,x')\,dF_x(x',t)dt}_{\text{Knowledge Gain from Poaching}} + \underbrace{\left(\mu(x) - \delta(t) - \frac{\sigma^2}{2}\right)dt + \sigma dW(t)}_{\text{R\&D}-\text{Creative Destruction}}$$

$$d\log n(x,t) = \underbrace{\frac{q(\theta(t))v(x,t)}{x}\int \mathbb{1}_P(x,x',t)dF_x(x',t)dt}_{\text{inventor inflow rate}} - \underbrace{\theta(t)\,q(\theta(t))\int \mathbb{1}_P(x',x,t)dF_v(x',t)dt}_{\text{inventor outflow rate}}$$

Back to the regression

Robustness of the Baseline Regression

	Zero-exposure sample			Lagged-outcome control	
	(1)	(2)	(3)	(4)	(5)
Diffusion exposure	0.3151^{***}	0.1803^{***}	0.1213^{**}	0.3127^{***}	0.2341^{**}
	(0.0519)	(0.0514)	(0.0613)	(0.0811)	(0.1006)
Lagged incumbent productivity growth				-0.1982^{***}	-0.1896^{***}
				(0.0180)	(0.0218)
Establishment FE	Yes	Yes	Yes	Yes	Yes
Year FE	Yes	No	No	No	No
Industry $\times$ region $\times$ year FE	No	Yes	Yes	Yes	Yes
Establishment-specific linear trend	No	No	Yes	No	Yes
Establishment-years	32,588	29,907	29,907	8,860	8,860

Columns (1)–(3) add establishment-years with zero exposure. All columns include the R&D exposure and the net inflow rate.

Back to estimate

Untargeted Productivity Dispersion

Moment	Data	Model
SD of log positive inventor productivity	1.08	0.89
P90/P50 of positive inventor productivity	2.94	3.24
P50/P10 of positive inventor productivity	4.81	3.15

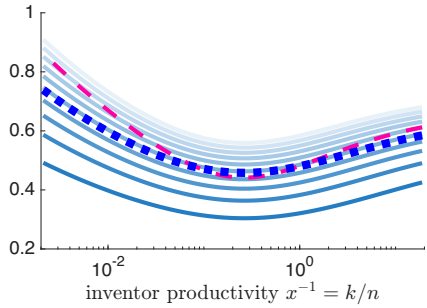

- The model understates overall and lower-tail dispersion and overstates the upper-tail ratio

Data: establishment-years with positive three-year citation productivity, 2001–2011, weighted by inventors. Model: inventor-weighted stationary distribution of k/n.

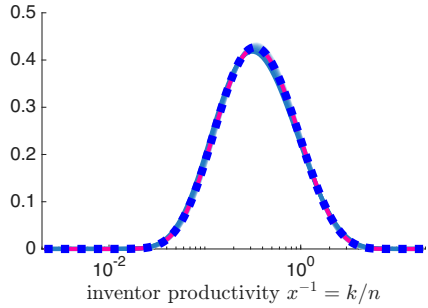

Back to calibration

Vacancy Posting Policy and Distribution

Vacancy posting policy $v(x)$

Inventor-weighted distribution $f_x(x)$

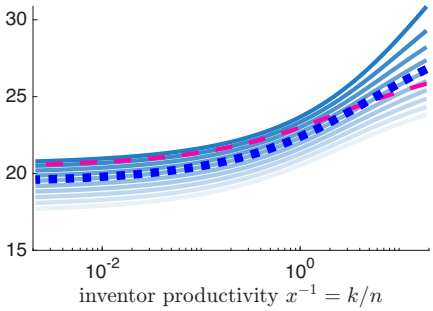

- $\beta \uparrow$ (The share of match surplus of poaching firms $\downarrow$) $\rightarrow$ Vacancy posting $\downarrow$

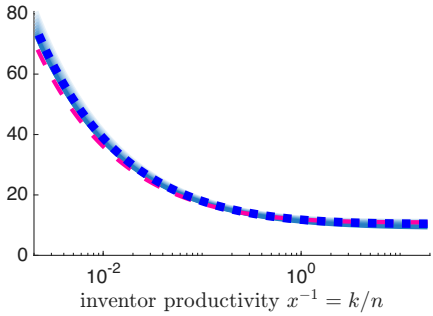

Horizontal axis: inventor productivity $x^{-1} = k/n$. Darker curves: larger $\beta = 0, 0.1, \ldots, 0.9$. Dashed: planner. Dotted: efficient split $\beta^* = 0.52$.

Marginal Value of Inventor & Marginal Value of Knowledge

$\Omega_n(k,n) = S_x(x)$

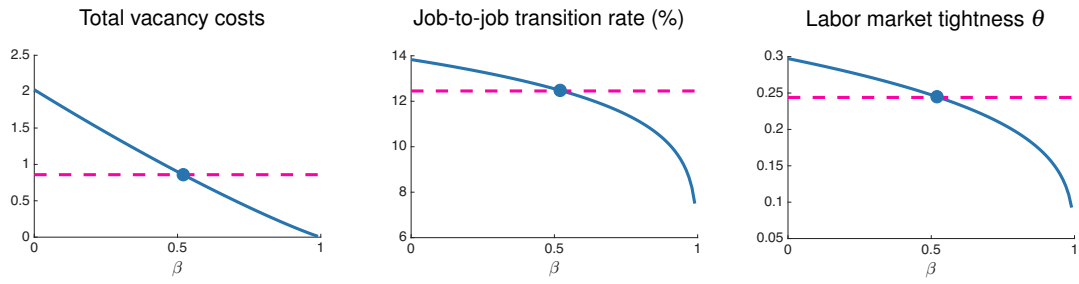

$\Omega_k(k,n) = S(x) - xS_x(x)$

Horizontal axis: inventor productivity $x^{-1} = k/n$. Darker curves: larger $\beta = 0, 0.1, \ldots, 0.9$. Dashed: planner. Dotted: efficient split $\beta^* = 0.52$.

Back to policy functions

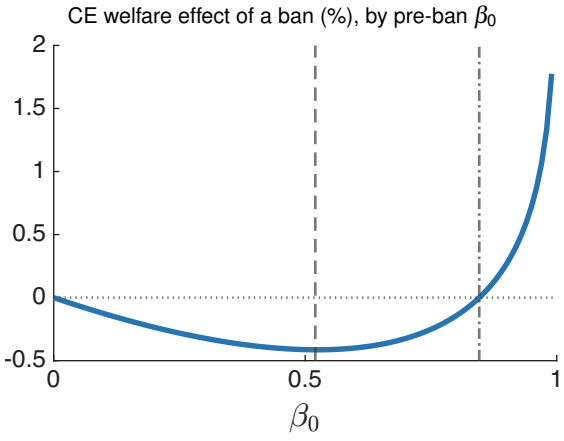

Vacancy Costs, Job-to-Job Rate, and Tightness

Steady states by β. Solid: equilibrium; dashed: planner; dot: efficient split $\beta^* = 0.52$.

Back to steady states

Welfare Effect of a Ban by Pre-Ban Surplus Share

- Every ban leads to the same BGP, so the welfare change tracks pre-ban welfare
- The loss is largest near the efficient split $\beta^* = 0.52$ (dashed line)
- A ban raises welfare only when the pre-ban surplus share exceeds 0.85 (dash-dotted line)

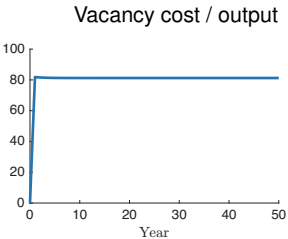

Back to fixed split

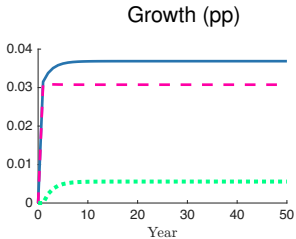

Efficient Split and Ban Welfare by Matching Elasticity

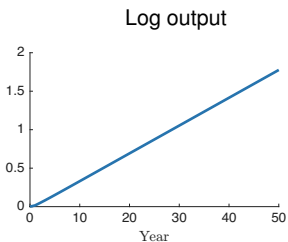

η	$1-\eta$	β^*	Gain at β^* (%)	Welfare change from ban (%)	Threshold β_0
0.3	0.70	0.71	0.0136	-0.66	0.98
0.4	0.60	0.62	0.0065	-0.54	0.93
0.5	0.50	0.52	0.0029	-0.41	0.85
0.6	0.40	0.43	0.0010	-0.28	0.74
0.7	0.30	0.34	0.0002	-0.13	0.62

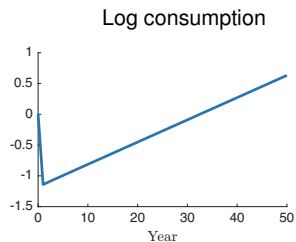

- $\overline{q}$ and λ are recalibrated for each η. β^* stays within 0.04 of $1-\eta$, and the ban lowers welfare at $\beta = 0.5$ for every η

Transition after a Ban

- Vacancy costs jump on impact; growth rises mainly through knowledge diffusion
- Output rises gradually; consumption falls on impact before recovering
- The growth gain from a ban rises from 0.037 pp at $\beta_0 = 0.5$ to 0.136 pp at $\beta_0 = 0.95$

Levels: 100 times the log deviation from the initial BGP. Growth: solid, total; dashed, knowledge diffusion; dotted, internal R&D. Horizontal axis: years.

Back to the ban

Consumption-Equivalent Welfare

$$\log C(t) = \log\lambda \int_0^t \delta(\tau)\, d\tau + \log L + \log\Big\{1 - \int c\big(v(x,t)\big)\, dF(x,t)\Big\}$$

$$V = \int_0^\infty e^{-\rho t} \log C(t)\, dt, \qquad \mathscr{L} = \exp\big[\rho\,\big(V(\widetilde{C}) - V(C)\big)\big]$$

- C: consumption on the initial BGP; $\widetilde{C}$: consumption after the change. Reported welfare changes are $100(\mathscr{L} - 1)$
- After the simulation horizon, consumption grows at the new steady-state rate

Matching-Efficiency Path

- The path's form follows Akcigit and Ates (2023)

$$\overline{q}_t = \overline{q}_0 + \frac{\exp(-\nu t/T) - 1}{\exp(-\nu) - 1}\left(\overline{q}_T - \overline{q}_0\right), \qquad t \in [0, T]$$

- $t = 0$ is 2001 and $t = T$ is 2014
- $\overline{q}_0 = 0.0198$ from the baseline; $\nu = 0.588$ and $\overline{q}_T = 0.00858$ match 8.3% in 2007 and 4.8% in 2014
- Unanticipated before $t = 0$, perfect foresight after. Matching efficiency stays at $\overline{q}_T$ after 2014 while the economy converges

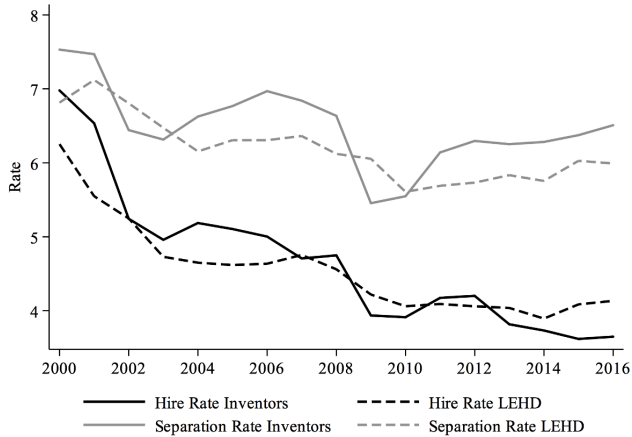

Back to mobility decline

German Inventor Job-to-Job Rates

Year	Inventor person-years	Job-to-job moves	Rate (%)
1999	117,904	14,358	12.2
2000	126,076	15,790	12.5
2001	129,050	16,194	12.5
2002	130,510	13,301	10.2
2003	130,597	11,180	8.6
2004	129,933	11,611	8.9
2005	129,425	10,093	7.8
